## COATING COMPOSITION AND PRINTING MEDIUM

The present invention is in respect of printing media which may be inkjet printed, to a method of inkjet printing on the printing media, and to coating compositions which may be used to form the printing media..

Inkjet printing produces little noise and can be used to print single color images or multicolor images on various substrates. Plain paper or paper having a low degree of sizing can be used as the printing substrate, but these suffer from the disadvantage that a clear image cannot be obtained because of the diffusion of the ink into the paper. More particularly, the image lacks sharp resolution, and in the case of color printing, the image lacks good optical density.

In order to achieve inkjet printed images of improved quality, coated papers have been employed as the printing substrates. The image quality varies depending upon the type of coating employed. In most instances image quality is better than that obtained using uncoated paper, but it is still less than desired.

Similarly, inkjet printing has been used to print single color images or multicolor images on organic polymer media, but spreading of the ink on organic polymer surfaces presents many problems, including lack of sharp image resolution, and in the case of color printing, the image lacks good optical density and wide color gamut. Coatings have provided some improvement, but image quality is still far less than desired.

Adhesion of coatings to paper substrates is often not a problem. However adhesion of inkjet printable coatings to organic polymer substrates has been a problem, especially in respect of polyolefin substrates.

Inkjet printing inks contain large amounts of solvents which, after printing, must either be permanently retained by the printing medium or, as is most common, evaporated. In order to avoid introduction of large amounts of organic materials into the environment, aqueous solvents which contain few, if any, organic materials, are generally used. Restriction to aqueous solvents, however, has heretofore resulted in coatings having low adhesion to organic polymer substrates and providing low quality images when inkjet printed.

Coating compositions have now been found which although based on aqueous solvents, do result in coatings of improved adhesion and high quality inkjet printed images.

Accordingly, one embodiment of the invention is a coating composition comprising: (a) volatile aqueous solvent; (b) binder dissolved in the volatile aqueous solvent, the binder comprising water-soluble poly[(meth)acrylic] acid and water-soluble poly(vinyl alcohol); and (c) particulate hydrophilic amorphous silica wherein at least 90 percent by weight of the particulate hydrophilic amorphous silica has gross particle sizes in the range of from 0.01 to 25  $\mu\text{m}$ .

Another embodiment of the invention is a printing medium comprising: (a) a substrate having at least one surface; and (b) a coating on the surface wherein the coating comprises: (1) binder comprising poly[(meth)acrylic] acid and poly(vinyl alcohol); and (2) particulate hydrophilic amorphous silica dispersed in the binder, wherein at least 90 percent by weight of the particulate hydrophilic amorphous silica has gross particle sizes in the range of from 0.01 to 25  $\mu\text{m}$ .

Yet another embodiment of the invention is a printing process which comprises applying liquid ink droplets to the printing medium of the second embodiment.

It is important that the poly[(meth)acrylic] acid, the poly(vinyl alcohol), and the hydrophilic particulate silica all be concurrently present in the coating compositions and the coatings of the printing media. Although it is  
5 desired not to be bound by any theory, it is believed that many improvements resulting from the present invention are due to the large numbers of sites available for hydrogen bonding among the three essential components of the coating.

The volatile aqueous solvent is predominately water.  
10 Small amounts of low boiling volatile water-miscible organic solvents may be intentionally added for particular purposes. Examples of such low boiling volatile water-miscible organic solvents include methanol [CAS 67-56-1], ethanol  
[CAS 64-17-5], 1-propanol, [CAS 71-23-8], 2-propanol  
15 [CAS 67-63-0], 2-butanol [CAS 78-92-2], 2-methyl-2-propanol [CAS 75-65-0], 2-propanone [CAS 67-64-1], and 2-butanone [CAS 78-93-3]. The listing of such solvents is by no means  
exhaustive.

It is preferred that substantially no low boiling  
20 volatile water-miscible organic materials be intentionally added to the system in order to minimize organic solvent emissions upon drying the coating.

Similarly, water-miscible organic solvents which are of low, moderate, or even negligible volatility may be  
25 intentionally added for particular purposes, such as for example, retardation of evaporation. Examples of such organic solvents include 2-methyl-1-propanol [CAS 78-83-1], 1-butanol [CAS 71-36-3], 1,2-ethanediol [CAS 107-21-1], and  
1,2,3-propanetriol [CAS 56-81-5]. The listing of such  
30 solvents is by no means exhaustive.

It is preferred that substantially no water-miscible organic solvents which are of low, moderate, or negligible volatility be intentionally added to the system.

Notwithstanding the above, those materials which, although not intentionally added for any particular purpose, are normally present as impurities in one or more the components of the coating compositions of the invention and  
5 which become components of the solvent, may be present at low concentrations.

In most instances water constitutes at least 80 percent by weight of the volatile aqueous solvent. Often water constitutes at least 95 percent by weight of the  
10 volatile aqueous solvent. Preferably water constitutes substantially all of the volatile aqueous solvent.

The water-soluble poly[(meth)acrylic acid] is water-soluble addition polymer formed by polymerizing monomer comprising acrylic acid [CAS 79-10-7], methacrylic acid  
15 [CAS 79-41-4], or both acrylic acid and methacrylic acid. Water-soluble poly[(meth)acrylic acid] and its preparation are both well known. See Encyclopedia of Polymer Science and Technology, vol. 1, John Wiley & Sons, New York (1964), Library of Congress Catalog Card Number 64-22188,  
20 pages 197-226, the disclosure of which is incorporated herein by reference. Acrylic and methacrylic acids are readily copolymerized with many other monomers. The poly[(meth)acrylic acid] may contain mer units of such other  
25 poly[(meth)acrylic acid] to be water-insoluble. Examples of monomers which may be copolymerized with acrylic acid and/or methacrylic acid include methyl acrylate, methyl methacrylate, 2-hydroxyethyl acrylate, styrene, and vinyl acetate. In most cases the poly[(meth)acrylic acid] is a homopolymer of acrylic  
30 acid, a homopolymer of methacrylic acid, or a copolymer of acrylic acid and methacrylic acid.

The weight average molecular weight of the water-soluble poly[(meth)acrylic acid] may vary widely. In general, the weight average molecular weight should be at least as large as will permit the poly[(meth)acrylic acid] to form  
5 films, but not so large as will render the binder insoluble in the volatile aqueous solvent. Usually the weight average molecular weight of the poly[(meth)acrylic acid] is in the range of from 100,000 to 1,000,000. Often the weight average molecular weight is in the range of from 150,000 to 500,000.  
10 From 200,000 to 300,000 is preferred.

The water-soluble poly(vinyl alcohol) and its preparation are both well known. See Encyclopedia of Polymer Science and Technology, vol. 14, John Wiley & Sons, New York (1971), Library of Congress Catalog Card Number 64-22188,  
15 pages 149-207, the disclosure of which is incorporated herein by reference. Water-soluble poly(vinyl alcohol) is usually made either by (1) direct hydrolysis of a poly(vinyl ester) or (2) ester interchange with an alcohol such as methanol or ethanol. Other processes are known, but little used. All of  
20 these processes will hereinafter be referred to collectively as "hydrolysis". By far the most common poly(vinyl ester) used in these processes is poly(vinyl acetate). In most cases the poly(vinyl acetate) is a homopolymer, so that the poly(vinyl alcohol) is a homopolymer if hydrolysis is  
25 complete, or a copolymer of vinyl alcohol and vinyl acetate if hydrolysis is less than complete. Since vinyl acetate can be copolymerized with many other monomers, vinyl alcohol copolymers are readily available by the hydrolysis of the vinyl acetate copolymers. Irrespective of whether other  
30 monomers are copolymerized with the vinyl acetate (or other vinyl ester), the numbers of hydroxyl groups present in the resulting poly(vinyl alcohol) are sufficient to render the poly(vinyl alcohol) water-soluble. In most instances the

- 6 -

water-soluble poly(vinyl alcohol) is characterized by a degree of hydrolysis of at least 75 percent. Often the water-soluble poly(vinyl alcohol) is characterized by a degree of hydrolysis of at least 80 percent. Preferably the degree of hydrolysis is at least 85 percent. As used herein and in the claims "degree of hydrolysis" is the ratio of the number of hydroxyl groups to the sum of the number of hydroxyl groups and the number of unreacted hydrolyzable ester groups present in the poly(vinyl alcohol), multiplied by one hundred. The degree of hydrolysis is expressed as percent.

The weight average molecular weight of the water-soluble poly(vinyl alcohol) may vary widely. In general, the weight average molecular weight should be at least as large as will permit the poly(vinyl alcohol) to form films, but not so large as will render the binder insoluble in the volatile aqueous solvent. Usually the weight average molecular weight of the water-soluble poly(vinyl alcohol) is in the range of from 100,000 to 400,000. Often the weight average molecular weight is in the range of from 110,000 to 300,000. From 120,000 to 200,000 is preferred.

The ratio of the hydroxyl equivalents of the water-soluble poly(vinyl alcohol) to the carboxyl equivalents of the water-soluble poly[(meth)acrylic acid] (hereinafter "the hydroxyl:carboxyl equivalent ratio") in the coating composition may vary considerably, but usually it is in the range of from 0.3:1 to 3:1. In many instances the hydroxyl:carboxyl equivalent ratio is in the range of from 0.5:1 to 2:1. From 0.7:1 to 1.5:1 is preferred.

Other thermoplastic film-forming organic polymer may also be present in the binder so long as its presence does not confer water-insolubility upon the binder of the coating composition or materially affect the properties of the coating in an adverse manner. The amount of the other thermoplastic

polymer which may be present depends upon the nature of such polymer. In general, a greater amount of other thermoplastic organic polymer may be used if the molecular structure contains many hydroxyl or carboxyl groups, than when there are  
5 few such groups. Usually the other thermoplastic polymer, when present, constitutes no more than 30 percent by weight of the binder. In most cases the other thermoplastic organic film-forming polymer is substantially absent.

The amount of poly(vinyl alcohol) and  
10 poly[(meth)acrylic acid] collectively present in the binder may also vary widely. In most instances the poly(vinyl alcohol) and the poly[(meth)acrylic acid] constitute from 70 to 100 percent by weight of the binder. Frequently the poly(vinyl alcohol) and the poly[(meth)acrylic acid]  
15 constitute from 85 to 100 percent by weight of the binder. From 95 to 100 percent by weight is preferred. It is especially preferred that the poly(vinyl alcohol) and the poly[(meth)acrylic acid] constitute substantially all of the binder.

20 Water-soluble crosslinking agents may optionally be present in the binder of the coating composition. These crosslinking agents are water-soluble compounds which will react with hydroxyl and/or carboxyl groups upon exposure of a coating formed from the coating composition to heat or other  
25 conditions which will cause the crosslinking reaction to ensue. Examples of suitable water-soluble crosslinking agents include low molecular weight melamine-aldehyde resin, low molecular weight resorcinol-aldehyde resin, low molecular weight phenol-aldehyde resin, glyoxal, gluteraldehyde,  
30 acetaldehyde, formaldehyde, boric acid, and sodium borate.

When present, water-soluble crosslinking agent usually constitutes less than 10 percent by weight of the binder. Preferably when present the water-soluble crosslinking agent constitutes less than 5 percent by weight of the binder.

5           Minor amounts, usually less than 5 percent by weight, of other materials introduced for particular purposes may optionally be present in the binder. Examples of such optional materials include surfactants, antioxidants, ultraviolet light absorbers, dyes, and the like. The balance  
10 of the binder is substantially thermoplastic organic polymer.

          All constituents of the binder of the coating composition are water-soluble. Although all constituents of the binder of the coating of the printing medium are usually water-soluble, this is not always so since one or more of such  
15 constituents may be crosslinked even to the point of water insolubility.

          Many different types of particulate hydrophilic amorphous silicas are known and have been used in a wide variety of applications. The most prevalent of the  
20 ~~particulate hydrophilic amorphous silicas are the particulate~~ hydrophilic amorphous precipitated silicas, the particulate hydrophilic amorphous silica gels, the colloidal particulate hydrophilic amorphous silicas, and the particulate hydrophilic amorphous fumed silicas. The particulate hydrophilic  
25 amorphous silica may be a single particulate hydrophilic amorphous silica, or it may be a mixture of two or more particulate hydrophilic amorphous silicas of the same type and/or of different types.

          It is important to distinguish amorphous  
30 precipitated silica from amorphous silica gel inasmuch as these different materials have different properties.

Reference in this regard is made to R. K. Iler, The Chemistry of Silica, John Wiley & Sons, New York (1979),

Library of Congress Catalog Card No. QD 181.S6144. Note especially pages 15-29, 172-176, 218-233, 364-365, 462-465, 554-564, and 578-579, the disclosures of which are incorporated herein by reference.

5           Amorphous silica gel is usually produced commercially at low pH by acidifying an aqueous solution of a soluble metal silicate, customarily sodium silicate, with acid. The acid employed is generally a strong mineral acid such as sulfuric acid or hydrochloric acid although carbon  
10   dioxide is sometimes used. Inasmuch as there is essentially no difference in density between the gel phase and the surrounding liquid phase while the viscosity is low, the gel phase does not settle out, that is to say, it does not precipitate. Silica gel, then, may be described as a  
15   non-precipitated, coherent, rigid, three-dimensional network of contiguous particles of colloidal amorphous silica. Following gel formation the liquid is removed by drying. The state of subdivision of amorphous silica gel ranges from large, solid masses to submicroscopic particles, and the  
20   degree of hydration from almost anhydrous silica to soft, gelatinous masses containing on the order of 100 parts of water per part of silica by weight, although the highly hydrated forms are only rarely used. Amorphous aerogel is a class of amorphous silica gel which is produced by (a) forming  
25   amorphous silica gel by acidification in the conventional manner, (b) replacing most of the water in the gel with a liquid such as 1-propanol which wets the surface of the silica gel pores, has a very low surface tension, and evaporates at ordinary temperature, and then (c) removing the liquid under  
30   pressure above the critical temperature of the alcohol so that there is no meniscus between the liquid and gas phases.

Amorphous precipitated silica is usually produced commercially by combining an aqueous solution of a soluble metal silicate, ordinarily alkali metal silicate such as sodium silicate, and an acid so that colloidal particles will  
5 grow in weakly alkaline solution and be coagulated by the alkali metal ions of the resulting soluble alkali metal salt.

Various acids may be used, including the mineral acids and/or carbon dioxide. In the absence of a coagulant, silica is not precipitated from solution at any pH. The coagulant used to  
10 effect precipitation may be the soluble alkali metal salt produced during formation of the colloidal silica particles, it may be added electrolyte such as a soluble inorganic or organic salt, or it may be a combination of both. Processes for producing amorphous precipitated silicas and the  
15 properties of the products are described in detail in United States Patents No. 2,657,149; 2,940,830; 4,132,806; 4,495,167, 4,681,750, and 5,094,829.

Amorphous precipitated silica, then, may be described as precipitated aggregates of ultimate particles of  
20 colloidal amorphous silica which aggregates have not at any point existed as macroscopic gel during the preparation. The sizes of the aggregates and the degree of hydration may vary widely.

Amorphous precipitated silica powders differ from  
25 amorphous silica gels that have been pulverized in ordinarily having a more open structure, that is, a higher specific pore volume. However, the specific surface area of amorphous precipitated silica as measured by the Brunauer, Emmett, Teller (BET) method using nitrogen as the adsorbate, is often  
30 lower than that of amorphous silica gel.

Variations in the parameters and/or conditions during production result in variations in the types of amorphous precipitated silicas produced. Although they are

- 11 -

all broadly amorphous precipitated silicas, the types of amorphous precipitated silicas often differ significantly in physical properties and sometimes in chemical properties. These differences in properties are important and often result in one type being especially useful for a particular purpose but of marginal utility for another purpose, whereas another type is quite useful for that other purpose but only marginally useful for the first purpose.

Colloidal amorphous silica is also known. Its preparation and properties are described by R. K. Iler in The Chemistry of Silica, John Wiley & Sons, Inc., New York (1979) ISBN 0-471-02404-X, pages 312-337, and in United States Patents No. 2,601,235; 2,614,993; 2,614,994; 2,617,995; 2,631,134; 2,885,366; and 2,951,044, the disclosures of which are, in their entireties, incorporated herein by reference. Examples of commercially available colloidal amorphous silica include Ludox® HS, LS, SM, TM and CL-X colloidal amorphous silica (E. I. du Pont de Nemours & Company, Inc.) in which the counter ion is the sodium ion, and Ludox® AS colloidal amorphous silica (E. I. du Pont de Nemours & Company, Inc.) in which the counter ion is the ammonium ion. Another example is Ludox® AM colloidal amorphous silica (E. I. du Pont de Nemours & Company, Inc.) in which some of the silicon atoms have been replaced by aluminum atoms and the counter ion is the sodium ion.

Amorphous fumed silica, also known as amorphous pyrogenic silica, is well known. It is formed at high temperature and is recovered from the gas phase as a voluminous, extremely finely divided powder. Amorphous fumed silica may be made by any of several pyrogenic processes, including (1) vaporizing silicon dioxide in an arc or plasma jet and condensing it in a stream of dry inert gas, (2) oxidizing silicon monoxide in the vapor phase with oxygen

- 12 -

and condensing the silicon dioxide, (3) oxidizing silicon compounds such as  $\text{SiH}_4$ ,  $\text{SiCl}_4$ , or  $\text{HSiCl}_3$  with oxygen in a hydrocarbon flame, (4) oxidizing silicon esters such as ethyl silicate; and (5) hydrolyzing  $\text{SiCl}_4$ ,  $\text{SiF}_4$ , or silicon esters such as methyl silicate, ethyl silicate, or butyl silicate at high temperatures. Other processes are known. See generally R. K. Iler, The Chemistry of Silica, John Wiley & Sons, New York (1979), Library of Congress Catalog Card No. QD181.S6144. Note especially pages 25, 336-337, 565-568, 613-614, and 632-633, the disclosures of which are incorporated herein by reference.

The hydrophilic amorphous silica used in the present invention is particulate. The particulate hydrophilic amorphous silica may be in the form of aggregates of ultimate particles, agglomerates of aggregates, or a combination of both. The gross particle sizes of the particulate hydrophilic amorphous silica used in the present invention may vary widely but ordinarily at least about 90 percent by weight of the particulate hydrophilic amorphous silica has gross particle sizes in the range of from 0.01 to 25 micrometers ( $\mu\text{m}$ ). Frequently at least about 90 percent by weight of the particulate hydrophilic amorphous silica has gross particle sizes in the range of from 0.05 to 20  $\mu\text{m}$ . In many cases at least about 90 percent by weight of the particulate hydrophilic amorphous silica has gross particle sizes in the range of from 0.1 to 10  $\mu\text{m}$ . Often at least 90 percent by weight of the amorphous silica has gross particle sizes in the range of from 0.1 to 5  $\mu\text{m}$ . Preferably at least 90 percent by weight of the particulate hydrophilic amorphous silica has gross particle sizes in the range of from 0.1 to 2  $\mu\text{m}$ . Size reduction and/or classification may be used to adjust gross particle sizes as necessary or as desired. Gross particle

sizes in the range of from about 0.01 to about 0.6  $\mu\text{m}$  are determined by photon correlation spectroscopy using a Coulter Model N4SD analyzer and size distribution processor analysis in accordance with the accompanying operating manual; see also

5 "Coulter® Model N4 series analyzers. Sizing by photon correlation spectroscopy." (Coulter Electronics, Inc., Hialeah, FL, 4 pages, 1987). Gross particle sizes in the range of from about 0.6 to about 125  $\mu\text{m}$  are determined by use of a Model TAPI Coulter Counter® (Coulter Electronics, Inc.)

10 according to ASTM C 690-80 but modified by stirring the amorphous silica particles for 10 minutes in Isoton® II electrolyte (Curtin Matheson Scientific, Inc.) using a four-blade, 4.45 centimeter diameter propeller stirrer. It is expected that the sizes of silica agglomerates may be reduced

15 during processing of the ingredients to prepare the coating composition. Accordingly, the distribution of gross particle sizes in the coating composition may be smaller than that of the raw amorphous silica used to prepare the coating composition.

20 The BET surface area of the dried particulate hydrophilic amorphous silica used in the present invention may vary widely. In many cases the BET surface area is in the range of from 100 to 1000 square meters per gram ( $\text{m}^2/\text{g}$ ). Often the BET surface area is in the range of from 100 to 500  $\text{m}^2/\text{g}$ .

25 From 125 to 225  $\text{m}^2/\text{g}$  is preferred. As used in the present specification and claims, the BET surface area of the dried amorphous silica is the surface area determined by the Brunauer, Emmett, Teller (BET) method according to ASTM C 1993-91 using nitrogen as the adsorbate.

30 The dibutyl phthalate ("DBP") oil absorption of the particulate hydrophilic amorphous silica used in the present invention may vary widely. In many instances the DBP oil absorption is in the range of from 100 to 300 cubic

- 14 -

centimeters per 100 grams ( $\text{cm}^3/100\text{g}$ ). Often the DBP oil absorption is in the range of from 150 to 250  $\text{cm}^3/100\text{g}$ . From 175 to 225  $\text{cm}^3/100\text{g}$  is preferred. As used in the present specification and claims, DBP oil absorption of the particles

5 is determined according to ASTM D 2414-93 using dibutyl phthalate [CAS 84-74-2] as the absorbate and a Type E Absorptometer with the procedure modified as follows: (1) a sample of amorphous silica weighing  $12.5 \pm 0.1$  grams (g) which is not further dried is introduced to the Type E

10 Absorptometer, (2) the moisture content of another sample of the amorphous silica weighing between 10 and 11 grams is determined using an Ohaus® moisture balance (Ohaus Corporation, Florham Park, NJ) with settings at 160°C and 10 minutes, and (3) the DBP oil absorption is calculated

15 from the equation:

$$OA = 100V/S + 3.9(M - 1.7)$$

where:

20 ~~OA is the DBP oil absorption,  $\text{cm}^3/100\text{g}$ ,~~

V is the volume of dibutyl phthalate used,  $\text{cm}^3$ ,  
S is the weight of the amorphous silica sample, g, and  
M is the moisture content, percent  $\text{H}_2\text{O}$  by weight.

25 The amorphous silica:binder weight ratio of the coating composition and of the coating of the coated substrate may vary widely but usually it is in the range of from 0.5:1 to 2:1. In many cases the amorphous silica:binder weight ratio is in the range of from 0.85:1 to 1.25:1. An amorphous

30 silica:binder weight ratio in the range of from 0.95:1 to 1.05:1 is preferred.

The amount of volatile aqueous solvent present in the coating compositions of the invention may vary very

widely. In general, at least enough volatile aqueous solvent should be present to dissolve the binder. The maximum amount is not limited by any theory, but by practical considerations such as the time and cost to remove the volatile aqueous solvent from the coating after application. In most cases the volatile aqueous solvent constitutes from 80 to 99 percent by weight of the coating composition. Often the volatile aqueous solvent constitutes from 82 to 95 percent by weight of the coating composition. From 4 to 90 percent by weight is preferred. Accordingly, the binder and the particulate hydrophilic amorphous silica collectively usually constitute from 1 to 20 percent by weight of the coating composition. Frequently the binder and the particulate hydrophilic amorphous silica collectively constitute from 5 to 18 percent by weight of the coating composition. From 10 to 16 percent by weight is preferred.

The coating compositions of the invention are usually prepared by simply admixing the various ingredients. Although the mixing is usually accomplished at room temperature, elevated temperatures are sometimes used. The maximum temperature which is usable depends upon the heat stability of the ingredients. Temperatures above about 100°C are only rarely employed.

The coating compositions of the invention are generally used to form adherent coatings on substrates. The substrate is coated with the coating composition using substantially any technique known to the art. These include spraying, curtain coating, dipping, roller application, printing, brushing, drawing, and extrusion.

Substrates which may be coated with the coating compositions of the invention may vary widely in their identities and their properties. The substrate may be transparent or it may be opaque. Organic substrates such as

- 16 -

wood, fiberboard, particle board, composition board, paper, cardboard and various polymers such as polyolefins (especially polyethylene and polypropylene), polyesters (especially poly(ethylene terephthalate)), polyamides, cured phenolic resins, cured aminoplasts, polystyrene, and poly(meth)acrylates. Inorganic substrates are exemplified by glass, quartz, and ceramic materials. Many metallic substrates may be coated. Exemplary metallic substrates are iron, steel, stainless steel, copper, brass, bronze, aluminum, magnesium, titanium, nickel, chromium, zinc, and alloys.

Other than in the operating examples, or where otherwise indicated, all numbers expressing quantities of ingredients or reaction conditions used herein are to be understood as modified in all instances by the term "about".

The invention is further described in conjunction with the following examples which are to be considered illustrative rather than limiting, and in which all parts are parts by weight and all percentages are percentages by weight unless otherwise specified.

#### EXAMPLE 1

A poly(vinyl alcohol) (PVOH) solution was formed by dissolving 100 grams polyvinyl alcohol (Airvol® 540; Air Products Inc., Allentown, PA) having a degree of hydrolysis of 87-89% and a weight average molecular weight of 124,000 - 186,000 in 900 grams of deionized water. The mixture was stirred at elevated temperature (80 - 90°C) until all polyvinyl alcohol was dissolved giving a composition containing approximately 10 percent solids by weight.

To 25 grams of the above PVOH solution was added 16.3 grams of a 25 percent by weight aqueous solution of poly(acrylic acid) (PAA) having a weight average molecular weight of 240,000, and 40 grams of deionized water. This

- 17 -

mixture was stirred to form a homogeneous solution. To the PVOH/PAA solution, 6.6 grams of a finely divided particulate hydrophilic amorphous precipitated silica (Hi-Sil® T-600; PPG Industries, Inc., Pittsburgh, PA) was added while stirring to form a coating composition.

The coating composition was applied to a polypropylene film having a thickness of 25.4 micrometers using a Meyer Rod #24 and allowed to dry under an infrared heating lamp. The dry coating was about 1 to 2 micrometers thick and exhibited good adhesion to the polypropylene film as demonstrated by a lack of cracking or delamination during a 180 degree flex/bend test.

The coated polypropylene film was then printed on the coated side by a Hewlett-Packard 1600C ink jet printer and a Hewlett-Packard 850C ink jet printer. The printed film showed good image quality and high color fidelity.

#### EXAMPLE 2

A coating composition was prepared as described in Example 1. The coating composition was applied to a poly(ethylene terephthalate) (PET) substrate using a Meyer Rod #24 and allowed to dry under an infrared heating lamp. The dry coating was approximately 1 to 2 micrometers thick and was translucent.

The coated PET substrate was then printed on the coated side by a Hewlett-Packard 1600C ink jet printer and a Hewlett-Packard 850C ink jet printer. The printed substrate showed good image quality and high color fidelity.

#### EXAMPLE 3

In a beaker, 16.5 grams of a 40% colloidal particulate hydrophilic amorphous silica solution (Ludox® HS-40; E. I. du Pont de Nemours & Co., Wilmington, DE) was added

- 18 -

to 16.3 grams of a 25 percent by weight aqueous solution of poly(acrylic acid) having a weight average molecular weight of 240,000. Addition of the colloidal silica solution to the PAA solution while stirring resulted in the solution turning milky white; however, no precipitate was observed. Next, 25 grams of the PVOH solution described in Example 1 was added to the PAA/colloidal silica mixture followed by an additional 25 grams of deionized water to form a coating composition.

The coating composition was applied to a polypropylene film having a thickness of 25.4 micrometers using a Meyer Rod #24 and allowed to dry under an infrared heating lamp. The dry coating was about 1 to 2 micrometers thick and exhibited good adhesion to the polypropylene film as demonstrated by a lack of cracking or delamination during a 180 degree bend/flex test.

The coated polypropylene film was then printed on the coated side by a Hewlett-Packard 850C ink jet printer. The printed film showed good image quality and high color fidelity.

#### EXAMPLE 4 (Comparative)

To 50.3 grams of the PVOH solution described in Example 1 was added 32.7 grams of a 25 percent aqueous solution of poly(acrylic acid) having a weight average molecular weight of 240,000 and 25 grams of deionized water. This mixture was stirred to form a homogeneous coating composition which contained no amorphous silica.

The coating composition was applied to a poly(ethylene terephthalate) substrate with a Meyer Rod #150 and allowed to dry under an infrared heating lamp. The dry coating was approximately 20 micrometers thick, clear, and sticky to the touch.

- 19 -

The coated PET substrate was then printed on the coated side by a Hewlett-Packard 1600C ink jet printer and a Hewlett-Packard 850C ink jet printer. The printed PET substrate exhibited unacceptable image quality with substantial cracking within the black pigmented regions.

#### EXAMPLE 5 (Comparative)

To 25 grams of the PVOH solution described in Example 1 was added 3 grams of a 40 percent by weight nonionic maleated polypropylene (PP) emulsion (Poly Emulsion 43N40; ChemCor Inc., Chester, NY) and 35 grams of deionized water. This mixture was stirred to form a homogeneous solution. To the PVOH/PP solution, 3.75 grams of a finely divided particulate hydrophilic amorphous precipitated silica (Hi-Sil® T-600; PPG Industries Inc., Pittsburgh, PA) was added while stirring to form a coating composition.

The coating composition was applied to a polypropylene film having a thickness of 25.4 micrometers using a Meyer Rod #24 and allowed to dry under an infrared heating lamp. The dry coating was about 1 to 2 micrometers thick and exhibited good adhesion to the polypropylene film.

The coated polypropylene film was then printed on the coated side by a Hewlett-Packard 1600C ink jet printer and a Hewlett-Packard 850C ink jet printer. The printed film showed poor image quality with a high amount of bleed.

Although the present invention has been described with reference to specific details of certain embodiments thereof, it is not intended that such details should be regarded as limitations upon the scope of the invention except insofar as they are included in the accompanying claims.

## CLAIMS:

1. A coating composition comprising:
  - (a) volatile aqueous solvent;
  - 5 (b) binder dissolved in the volatile aqueous solvent, the binder comprising water-soluble poly[(meth)acrylic] acid and water-soluble poly(vinyl alcohol); and
  - 10 (c) particulate hydrophilic amorphous silica wherein at least 90 percent by weight of the particulate hydrophilic amorphous silica has gross particle sizes in the range of from 0.01 to 25  $\mu\text{m}$ .
- 15 2. The coating composition of claim 1 wherein water constitutes at least 95 percent by weight of the volatile aqueous solvent.
- 20 3. The coating composition of claim 1 wherein water constitutes substantially all of the volatile aqueous solvent.
- 25 4. The coating composition of claim 1 wherein the water-soluble poly[(meth)acrylic] acid is water-soluble poly(acrylic acid).
- 30 5. The coating composition of claim 1 wherein the water-soluble poly[(meth)acrylic] acid is water-soluble poly(methacrylic acid).
6. The coating composition of claim 1 wherein the water-soluble poly[(meth)acrylic] acid is a water-soluble copolymer of acrylic acid and methacrylic acid.

7. The coating composition of claim 1 wherein the weight average molecular weight of the water-soluble poly[(meth)acrylic] acid is in the range of from 100,000 to 1,000,000.

8. The coating composition of claim 1 wherein the degree of hydrolysis of the water-soluble poly(vinyl alcohol) is at least .5 percent.

9. The coating composition of claim 1 wherein the weight average molecular weight of the water-soluble poly(vinyl alcohol) is in the range of from 100,000 to 400,000.

10. The coating composition of claim 1 wherein the hydroxyl:carboxyl equivalent ratio is in the range of from 0.3:1 to 3:1.

11. The coating composition of claim 1 wherein the water-soluble poly[(meth)acrylic] acid and the water-soluble poly(vinyl alcohol) constitute from 70 to 100 percent by weight of the binder.

12. The coating composition of claim 1 wherein the water-soluble poly[(meth)acrylic] acid and the water-soluble poly(vinyl alcohol) constitute substantially all of the binder.

13. The coating composition of claim 1 wherein the binder comprises water-soluble crosslinking agent and wherein the water-soluble crosslinking agent constitutes less than 10 percent by weight of the binder.

14. The coating composition of claim 1 wherein the particulate hydrophilic amorphous silica is particulate hydrophilic amorphous precipitated silica.

5

15. The coating composition of claim 1 wherein:

- (a) the BET surface area of the particulate hydrophilic amorphous silica is in the range of from 100 to 1000 m<sup>2</sup>/g, and
- (b) the DBP oil absorption of the particulate hydrophilic amorphous silica is in the range of from 100 to 300 cm<sup>3</sup>/100g.

10

16. The coating composition of claim 1 wherein the amorphous silica:binder ratio is in the range of from 0.5:1 to 2:1.

15

17. The coating composition of claim 1 wherein:

- (a) the volatile aqueous solvent constitutes from 80 to 99 percent by weight of the coating composition, and
- (b) the binder and the particulate hydrophilic amorphous silica collectively constitute from 1 to 20 percent by weight of the coating composition.

20

25

18. A printing medium comprising:

- (a) a substrate having at least one surface; and
- (b) a coating on the surface wherein the coating comprises:

- 5 (1) binder comprising poly[(meth)acrylic] acid and poly(vinyl alcohol); and
- (2) particulate hydrophilic amorphous silica dispersed in the binder, wherein at least 90 percent by weight of the particulate
- 10 hydrophilic amorphous silica has gross particle sizes in the range of from 0.01 to 25  $\mu\text{m}$ .

19. The printing medium of claim 18 wherein the  
15 poly[(meth)acrylic] acid is poly(acrylic acid).

20. The printing medium of claim 18 wherein the  
poly[(meth)acrylic] acid is poly(methacrylic acid).

20 21. The printing medium of claim 18 wherein the  
poly[(meth)acrylic] acid is a copolymer of acrylic acid and  
methacrylic acid.

22. The printing medium of claim 18 wherein the  
25 weight average molecular weight of the poly[(meth)acrylic]  
acid is in the range of from 100,000 to 1,000,000.

23. The printing medium of claim 18 wherein the  
degree of hydrolysis of the poly(vinyl alcohol) is at least 75  
30 percent.

- 24 -

24. The printing medium of claim 18 wherein the weight average molecular weight of the poly(vinyl alcohol) is in the range of from 100,000 to 400,000.

5 25. The printing medium of claim 18 wherein the hydroxyl:carboxyl equivalent ratio is in the range of from 0.3:1 to 3:1.

26. The printing medium of claim 18 wherein the  
10 poly[(meth)acrylic] acid and the poly(vinyl alcohol) constitute from 70 to 100 percent by weight of the binder.

27. The printing medium of claim 18 wherein the  
15 poly[(meth)acrylic] acid and the poly(vinyl alcohol) constitute substantially all of the binder.

28. The printing medium of claim 18 wherein the binder comprises crosslinking agent and wherein the crosslinking agent constitutes less than 10 percent by weight  
20 of the binder.

29. The printing medium of claim 18 wherein the particulate hydrophilic amorphous silica is particulate hydrophilic amorphous precipitated silica.

25

30. The printing medium of claim 18 wherein:  
(a) the BET surface area of the particulate hydrophilic amorphous silica is in the range of from 100 to 1000 m<sup>2</sup>/g, and  
30 (b) the DBP oil absorption of the particulate hydrophilic amorphous silica is in the range of from 100 to 300 cm<sup>3</sup>/100g.

31. The printing medium of claim 18 wherein the amorphous silica:binder ratio is in the range of from 0.5:1 to 2:1.

5 32. The printing medium of claim 18 wherein the binder and the particulate hydrophilic amorphous silica collectively constitute from 1 to 20 percent by weight of the coating.

10 33. The printing medium of claim 18 wherein the substrate is transparent.

34. The printing medium of claim 18 wherein the substrate is opaque.

15

35. A printing process which comprises applying liquid ink droplets to the printing medium of claim 18.
